

Exercice Lab: Logistic Regression

<https://www.coursera.org/learn/machine-learning-with-python/ungradedLti/TzBLF/lab-logistic-regression>

In this notebook, you will learn Logistic Regression, and then, you'll create a model with telecommunications data to predict when its customers will leave for a competitor, so that you can take some action to retain the customer.

Please notice that the practice labs (except the last week assignment) are optional and are provided for you to practice and understand the topic. Therefore, you do not need to submit those, as they are not graded, and won't be updated as complete. Just run the codes to see the results, and feel free to change it.

Ce cours utilise l'outil d'un tiers, Lab: Logistic Regression, pour améliorer votre expérience d'apprentissage. L'outil référence des informations de base comme votre nom, votre adresse e-mail et votre ID Coursera.

Logistic Regression with Python

In this notebook, you will learn Logistic Regression, and then, you'll create a model for a telecommunication company, to predict when its customers will leave for a competitor, so that they can take some action to retain the customers.

What is the difference between Linear and Logistic Regression?

While Linear Regression is suited for estimating continuous values (e.g. estimating house price), it is not the best tool for predicting the class of an observed data point. In order to estimate the class of a data point, we need some sort of guidance on what would be the **most probable class** for that data point. For this, we use **Logistic Regression**.

Recall linear regression:

As you know, **Linear regression** finds a function that relates a continuous dependent variable, \mathbf{y} , to some predictors (independent variables x_1, x_2 , etc.). For example, Simple linear regression assumes a function of the form:

$$y = \theta_0 + \theta_1 x_1 + \theta_2 x_2 + \dots$$

and finds the values of parameters $\theta_0, \theta_1, \theta_2$, etc, where the term θ_0 is the "intercept". It can be generally shown as:

$$h_{\theta}(x) = \theta^T X$$

Logistic Regression is a variation of Linear Regression, useful when the observed dependent variable, \mathbf{y} , is categorical. It produces a formula that predicts the probability of the class label as a function of the independent variables.

Logistic regression fits a special s-shaped curve by taking the linear regression and transforming the numeric estimate into a probability with the following function, which is called sigmoid function σ :

$$h_{\theta}(x) = \sigma(\theta^T X) = \frac{e^{(\theta_0 + \theta_1 x_1 + \theta_2 x_2 + \dots)}}{1 + e^{(\theta_0 + \theta_1 x_1 + \theta_2 x_2 + \dots)}}$$

Or:

$$\text{ProbabilityOfaClass}_1 = P(Y = 1|X) = \sigma(\theta^T X) = \frac{e^{\theta^T X}}{1 + e^{\theta^T X}}$$

In this equation, $\theta^T X$ is the regression result (the sum of the variables weighted by the coefficients), \exp is the exponential function and $\sigma(\theta^T X)$ is the sigmoid or **logistic function**, also called logistic curve. It is a common "S" shape (sigmoid curve).

So, briefly, Logistic Regression passes the input through the logistic/sigmoid but then treats the result as a probability:

The objective of **Logistic Regression** algorithm, is to find the best parameters θ , for $h_{\theta}(x) = \sigma(\theta^T X)$, in such a way that the model best predicts the class of each case.

Customer churn with Logistic Regression

A telecommunications company is concerned about the number of customers leaving their land-line business for cable competitors. They need to understand who is leaving. Imagine that you are an analyst at this company and you have to find out who is leaving and why.

Lets first import required libraries:

```
[ ]: import pandas as pd
      import pylab as pl
      import numpy as np
      import scipy.optimize as opt
      from sklearn import preprocessing
      %matplotlib inline
      import matplotlib.pyplot as plt
```

Code

```
import pandas as pd
import pylab as pl
import numpy as np
import scipy.optimize as opt
from sklearn import preprocessing
%matplotlib inline
import matplotlib.pyplot as plt
```

About the dataset

We will use a telecommunications dataset for predicting customer churn. This is a historical customer dataset where each row represents one customer. The data is relatively easy to understand, and you may uncover insights you can use immediately. Typically it is less expensive to keep customers than acquire new ones, so the focus of this analysis is to predict the customers who will stay with the company.

This data set provides information to help you predict what behavior will help you to retain customers. You can analyze all relevant customer data and develop focused customer retention programs.

The dataset includes information about:

- Customers who left within the last month – the column is called Churn
- Services that each customer has signed up for – phone, multiple lines, internet, online security, online backup, device protection, tech support, and streaming TV and movies
- Customer account information – how long they had been a customer, contract, payment method,

paperless billing, monthly charges, and total charges

- Demographic info about customers – gender, age range, and if they have partners and dependents

Load the Telco Churn data

Telco Churn is a hypothetical data file that concerns a telecommunications company's efforts to reduce turnover in its customer base. Each case corresponds to a separate customer and it records various demographic and service usage information. Before you can work with the data, you must use the URL to get the ChurnData.csv.

To download the data, we will use `!wget` to download it from IBM Object Storage.

```
[ ]: #Click here and press Shift+Enter
!wget -O ChurnData.csv https://s3-api.us-geo.objectstorage.softlayer.net/cf-courses-data/Cognit
```

Code

```
#Click here and press Shift+Enter
!wget -O ChurnData.csv https://s3-api.us-geo.objectstorage.softlayer.net/cf-courses-data/CognitiveClass/ML0101ENv3/labs/ChurnData.csv
```

Load Data From CSV File

```
[ ]: churn_df = pd.read_csv("ChurnData.csv")
churn_df.head()
```

Code

```
churn_df = pd.read_csv("ChurnData.csv")
churn_df.head()
```

```
[3]:   tenure  age  address  income  ed  employ  equip  callcard  wireless  longmon  ...  pager  internet  callwait

```

5 rows × 28 columns

Data pre-processing and selection

Lets select some features for the modeling. Also we change the target data type to be integer, as it is a requirement by the sklearn algorithm:

```
[ ]: churn_df = churn_df[['tenure', 'age', 'address', 'income', 'ed', 'employ', 'equip',   'callcard',
churn_df['churn'] = churn_df['churn'].astype('int')
churn_df.head()
```

Code

```
churn_df = churn_df[['tenure', 'age', 'address', 'income', 'ed', 'employ', 'equip',   'callcard', 'wireless','churn']]
churn_df['churn'] = churn_df['churn'].astype('int')
churn_df.head()
```

Practice

How many rows and columns are in this dataset in total? What are the name of columns?

```
[ ]: # write your code here  
churn_df.shape
```

Lets define X, and y for our dataset:

```
[ ]: X = np.asarray(churn_df[['tenure', 'age', 'address', 'income', 'ed', 'employ', 'equip']])  
X[0:5]
```

Code

```
X = np.asarray(churn_df[['tenure', 'age', 'address', 'income', 'ed', 'employ', 'equip']])  
X[0:5]
```

```
[6]: array([[ 11.,  33.,   7., 136.,   5.,   5.,   0.],  
           [ 33.,  33.,  12.,  33.,   2.,   0.,   0.],  
           [ 23.,  30.,   9.,  30.,   1.,   2.,   0.],  
           [ 38.,  35.,   5.,  76.,   2.,  10.,   1.],  
           [  7.,  35.,  14.,  80.,   2.,  15.,   0.]])
```

```
[ ]: y = np.asarray(churn_df['churn'])  
y [0:5]
```

```
[7]: array([1, 1, 0, 0, 0])
```

Code

```
y = np.asarray(churn_df['churn'])  
y[0:5]
```

Also, we normalize the dataset:

```
[ ]: from sklearn import preprocessing  
X = preprocessing.StandardScaler().fit(X).transform(X)  
X[0:5]
```

Code

```
from sklearn import preprocessing  
X = preprocessing.StandardScaler().fit(X).transform(X)  
X[0:5]  
  
[9]: array([[-1.13518441, -0.62595491, -0.4588971 ,  0.4751423 ,  1.6961288 ,  
           -0.58477841, -0.85972695],  
           [-0.11604313, -0.62595491,  0.03454064, -0.32886061, -0.6433592 ,  
           -1.14437497, -0.85972695],  
           [-0.57928917, -0.85594447, -0.261522 , -0.35227817, -1.42318853,  
           -0.92053635, -0.85972695],  
           [ 0.11557989, -0.47262854, -0.65627219,  0.00679109, -0.6433592 ,  
           -0.02518185,  1.16316  ],  
           [-1.32048283, -0.47262854,  0.23191574,  0.03801451, -0.6433592 ,  
           0.53441472, -0.85972695]])
```

Train/Test dataset

Okay, we split our dataset into train and test set:

```
[ ]: from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split( X, y, test_size=0.2, random_state=4)
print ('Train set:', X_train.shape, y_train.shape)
print ('Test set:', X_test.shape, y_test.shape)
```

Code

```
from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split( X, y, test_size=0.2, random_state=4)
print ('Train set:', X_train.shape, y_train.shape)
print ('Test set:', X_test.shape, y_test.shape)
```

Modeling (Logistic Regression with Scikit-learn)

Lets build our model using **LogisticRegression** from Scikit-learn package. This function implements logistic regression and can use different numerical optimizers to find parameters, including 'newton-cg', 'lbfgs', 'liblinear', 'sag', 'saga' solvers. You can find extensive information about the pros and cons of these optimizers if you search it in internet.

The version of Logistic Regression in Scikit-learn, support regularization. Regularization is a technique used to solve the overfitting problem in machine learning models. **C** parameter indicates **inverse of regularization strength** which must be a positive float. Smaller values specify stronger regularization. Now lets fit our model with train set:

```
[ ]: from sklearn.linear_model import LogisticRegression
from sklearn.metrics import confusion_matrix
LR = LogisticRegression(C=0.01, solver='liblinear').fit(X_train,y_train)
LR
```

Code

```
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import confusion_matrix
LR = LogisticRegression(C=0.01, solver='liblinear').fit(X_train,y_train)
LR
[9]: LogisticRegression(C=0.01, class_weight=None, dual=False, fit_intercept=True,
intercept_scaling=1, max_iter=100, multi_class='warn',
n_jobs=None, penalty='l2', random_state=None, solver='liblinear',
tol=0.0001, verbose=0, warm_start=False)
```

Now we can predict using our test set:

```
[ ]: yhat = LR.predict(X_test)
yhat
```

Code

```
yhat = LR.predict(X_test)
yhat
[10]: array([0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0,
0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0])
```

predict_proba returns estimates for all classes, ordered by the label of classes. So, the first column is the probability of class 1, $P(Y=1|X)$, and second column is probability of class 0, $P(Y=0|X)$:

```
[11]: yhat_prob = LR.predict_proba(X_test)
yhat_prob
```

Code

```
yhat_prob = LR.predict_proba(X_test)
yhat_prob
```

```
[11]: array([[0.85690857, 0.14309143],

 [0.96939574, 0.03060426],
 [0.86392762, 0.13607238]])
```

Evaluation

jaccard index

Lets try jaccard index for accuracy evaluation. we can define jaccard as the size of the intersection divided by the size of the union of two label sets. If the entire set of predicted labels for a sample strictly match with the true set of labels, then the subset accuracy is 1.0; otherwise it is 0.0.

```
[ ]: from sklearn.metrics import jaccard_similarity_score
jaccard_similarity_score(y_test, yhat)
```

Code

```
from sklearn.metrics import jaccard_similarity_score
jaccard_similarity_score(y_test, yhat)
```

confusion matrix

Another way of looking at accuracy of classifier is to look at **confusion matrix**.

```
[ ]: from sklearn.metrics import classification_report, confusion_matrix
import itertools
def plot_confusion_matrix(cm, classes,
                         normalize=False,
                         title='Confusion matrix',
                         cmap=plt.cm.Blues):
    """
    This function prints and plots the confusion matrix.
    Normalization can be applied by setting `normalize=True`.
    """
    if normalize:
        cm = cm.astype('float') / cm.sum(axis=1)[:, np.newaxis]
        print("Normalized confusion matrix")
    else:
        print('Confusion matrix, without normalization')

    print(cm)

    plt.imshow(cm, interpolation='nearest', cmap=cmap)
    plt.title(title)
    plt.colorbar()
    tick_marks = np.arange(len(classes))
    plt.xticks(tick_marks, classes, rotation=45)
    plt.yticks(tick_marks, classes)

    fmt = '.2f' if normalize else 'd'
    thresh = cm.max() / 2.
    for i, j in itertools.product(range(cm.shape[0]), range(cm.shape[1])):
        plt.text(j, i, format(cm[i, j], fmt),
                 horizontalalignment="center",
                 color="white" if cm[i, j] > thresh else "black")

    plt.tight_layout()
    plt.ylabel('True label')
    plt.xlabel('Predicted label')
print(confusion_matrix(y_test, yhat, labels=[1,0]))
```

Code

```
from sklearn.metrics import classification_report, confusion_matrix
```

```
import itertools
```

```
def plot_confusion_matrix(cm, classes,
```

```
                         normalize=False,
```

```
                         title='Confusion matrix',
```

```
                         cmap=plt.cm.Blues):
```

```
"""
This function prints and plots the confusion matrix.
Normalization can be applied by setting `normalize=True`.
"""
if normalize:
```

```
    cm = cm.astype('float') / cm.sum(axis=1)[:, np.newaxis]
```

```

print("Normalized confusion matrix")
else:
    print('Confusion matrix, without normalization')

print(cm)

plt.imshow(cm, interpolation='nearest', cmap=cmap)
plt.title(title)
plt.colorbar()
tick_marks = np.arange(len(classes))
plt.xticks(tick_marks, classes, rotation=45)
plt.yticks(tick_marks, classes)

fmt = '.2f' if normalize else 'd'
thresh = cm.max() / 2.
for i, j in itertools.product(range(cm.shape[0]), range(cm.shape[1])):
    plt.text(j, i, format(cm[i, j], fmt),
             horizontalalignment="center",
             color="white" if cm[i, j] > thresh else "black")

plt.tight_layout()
plt.ylabel('True label')
plt.xlabel('Predicted label')
print(confusion_matrix(y_test, yhat, labels=[1,0]))

```

```

[ ]: # Compute confusion matrix
cnf_matrix = confusion_matrix(y_test, yhat, labels=[1,0])
np.set_printoptions(precision=2)

# Plot non-normalized confusion matrix
plt.figure()
plot_confusion_matrix(cnf_matrix, classes=['churn=1', 'churn=0'], normalize=False, title='Confu

```

Code

```

# Compute confusion matrix
cnf_matrix = confusion_matrix(y_test, yhat, labels=[1,0])
np.set_printoptions(precision=2)

```

```

# Plot non-normalized confusion matrix
plt.figure()
plot_confusion_matrix(cnf_matrix, classes=['churn=1', 'churn=0'], normalize=False, title='Confusion matrix')

```

```
Confusion matrix, without normalization
[[ 6  9]
 [ 1 24]]
```

Look at first row. The first row is for customers whose actual churn value in test set is 1. As you can calculate, out of 40 customers, the churn value of 15 of them is 1. And out of these 15, the classifier correctly predicted 6 of them as 1, and 9 of them as 0.

It means, for 6 customers, the actual churn value were 1 in test set, and classifier also correctly predicted those as 1. However, while the actual label of 9 customers were 1, the classifier predicted those as 0, which is not very good. We can consider it as error of the model for first row.

What about the customers with churn value 0? Lets look at the second row. It looks like there were 25 customers whom their churn value were 0.

The classifier correctly predicted 24 of them as 0, and one of them wrongly as 1. So, it has done a good job in predicting the customers with churn value 0. A good thing about confusion matrix is that shows the model's ability to correctly predict or separate the classes. In specific case of binary classifier, such as this example, we can interpret these numbers as the count of true positives, false positives, true negatives, and false negatives.

```
[ ]: print (classification_report(y_test, yhat))
```

Code

```
print (classification_report(y_test, yhat))
      precision    recall  f1-score   support

          0       0.73     0.96     0.83      25
          1       0.86     0.40     0.55      15

   micro avg       0.75     0.75     0.75      40
   macro avg       0.79     0.68     0.69      40
weighted avg       0.78     0.75     0.72      40
```

Based on the count of each section, we can calculate precision and recall of each label:

- **Precision** is a measure of the accuracy provided that a class label has been predicted. It is defined by:
$$\text{precision} = \text{TP} / (\text{TP} + \text{FP})$$
- **Recall** is true positive rate. It is defined as: $\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$

So, we can calculate precision and recall of each class.

F1 score: Now we are in the position to calculate the F1 scores for each label based on the precision and recall of that label.

The F1 score is the harmonic average of the precision and recall, where an F1 score reaches its best value at 1 (perfect precision and recall) and worst at 0. It is a good way to show that a classifier has a good value for both recall and precision.

And finally, we can tell the average accuracy for this classifier is the average of the F1-score for both labels, which is 0.72 in our case.

log loss

Now, lets try **log loss** for evaluation. In logistic regression, the output can be the probability of customer churn is yes (or equals to 1). This probability is a value between 0 and 1. Log loss(Logarithmic loss) measures the performance of a classifier where the predicted output is a probability value between 0 and 1.

```
[ ]: from sklearn.metrics import log_loss  
log_loss(y_test, yhat_prob)
```

Code

```
from sklearn.metrics import log_loss  
log_loss(y_test, yhat_prob)
```

Practice

Try to build Logistic Regression model again for the same dataset, but this time, use different `_solver_` and `_regularization_` values? What is new `_logLoss_` value?

```
[ ]: # write your code here
```

Double-click `_here_` for the solution.

`<!-- Your answer is below:`

```
LR2 = LogisticRegression(C=0.01, solver='sag').fit(X_train,y_train)  
yhat_prob2 = LR2.predict_proba(X_test)  
print ("LogLoss: : %.2f" % Log_Loss(y_test, yhat_prob2))  
-->
```

Code

Double-click here for the solution.

<!-- Your answer is below:

```
LR2 = LogisticRegression(C=0.01, solver='sag').fit(X_train,y_train)
yhat_prob2 = LR2.predict_proba(X_test)
print ("LogLoss: : %.2f" % log_loss(y_test, yhat_prob2))
```

IBM SPSS Modeler is a comprehensive analytics platform that has many machine learning algorithms. It has been designed to bring predictive intelligence to decisions made by individuals, by groups, by systems – by your enterprise as a whole. A free trial is available through this course, available here: [SPSS Modeler](#)

Also, you can use Watson Studio to run these notebooks faster with bigger datasets. Watson Studio is IBM's leading cloud solution for data scientists, built by data scientists. With Jupyter notebooks, RStudio, Apache Spark and popular libraries pre-packaged in the cloud, Watson Studio enables data scientists to collaborate on their projects without having to install anything. Join the fast-growing community of Watson Studio users today with a free account at [Watson Studio](#)
